Version 1

What is Agile Software Development? First we must break down the word, so Agile means the ability to adapt to anything out of the ordinary. Development is the process of creating or developing something. Software is the program run by a computer. Now Agile Software Development is a broad term for the many terms and methodologies. Agile Software Development is basically when people create new software in groups and team rather than individually.

The textbook explains how coding is more complex than just writing the code and how many steps are involved, but unlike Agile Software Development the same person is required to perform all of the vast steps. In Agile Software Development a group of people are working together so a big project is not so big anymore. Some short coming of Agile Development is that sometimes the direction say your team wants to go in is not what is in your best interest. A potential downfall of handing all the development process on your own is that you creative genius is being limited because you become focused on the entire process. In my opinion I would want to use Agile Software Development ideologies, because I believe the more minds the better the potential product.
